Introduction

Authoring is a common task for all scholars and students in academia, from report preparation, teaching, journal submission to book writing. Yet many people in academia aren't familiar with using specialized tools and an integrated workflow for academic writing, especially in the fields of Social science.

Academic writing takes a great deal of time. However, much of the time spent *isn't related to the content or the idea the author wishes to convey* but the chores regarding repetitive works such as manually combining results from different analysis tools or formatting the papers to suit the requirements of journals. A great deal of time can be saved if there exists a recommended and integrated workflow for academic writing, either as a norm or a culture that encourages this. Currently, however, workflows for academic writing are a matter of tastes for different authors and are considered as personal skills. It should be argued that a workflow be proposed in a specific field of science, especially in the fields of Social science, where students often have no formal programming training to allow themselves to build custom programs that facilitate an integrated workflow.

An integrated workflow for academic writing is crucial in science. An example of a common, but not integrated, workflow is illustrated below:

Figure 1: A common but not integrated workflow (Munzert, Rubba, Meißner, & Nyhuis, 2014, pp xviii).

One of the problem of this workflow is that authors have to manually copy-and-paste results from different sources, which are error-prone, and when errors are found, authors have to go through the process again, wasting a substantial time. An even more serious problem related to this workflow is that it might hinder the progress of science, since when errors occurred but are not found, erroneous results enter a published paper, in which subsequent researches would base on.

Facilitating an integrated workflow for academic writing is related to specific tasks a field often does. Hence, no preexisting tools exist. However, general frameworks exist and are extendable and customizable to fit in specific needs of a field. This article surveys the R Markdown ecosystem, and focuses particularly on features related to Linguistics in order to propose a integrated workflow for authoring.

Overview of R Markdown

A Brief Introduction to R Markdown

“Markdown” is a minimalist and easy-to-learn markup language¹, which formats the text by using plain text markers, e.g., lines beginning with “#” are first level titles and “##” are second level titles, wrapping text with “*” results in italics, etc. “R Markdown” extends the syntax of Markdown to allow more versatile styling of the text and therefore allows authoring documents with publication-ready qualities.

Benefits of Using R Markdown

There are several benefits for using R Markdown as an authoring tool. Most of them results directly from the extensibility of R, the language R Markdown bases on.

R

The core feature of R Markdown is its integration with R, a programming language developed not in a traditional CS²-context but for the purpose of statistical computing (R Core Team, 2018). This makes R an special language – although R has a steep learning curve compared to other GUI-based statistical softwares, it has a gentle learning curve compared to other “hardcore” programming languages. R is designed for scientists, not programmers. In addition, R has a huge and friendly community support, which means solutions to many problems new users often confront can easily be found on the web.

Many fields other than statistics either start to or already use R substantially, such as Biostatistics and Bioinformatics, Ecology and Evolution, Finance, Psychometrics, Geospatial analysis, and even Linguistics

¹Markup languages are used to style text appearance. For example, HTML (Hyper Text Markup Language) is one of the most popular markup language, which is used to format web pages.

²Abbreviation for Computer science.

(CRAN, 2018b). This is due to R's great extensibility, with more than 13,000 packages hosted on CRAN (2018a). As noted later, this extensibility also enables turning R Markdown into a specialized tool for authoring in a particular field.

By integration with R language, R Markdown allows computed results be directly embedded into the document. To put it another way, the analysis of data (through R) is directly integrated into document writing, and hence, errors incurred by manual copy-and-paste are eliminated. This also enhance the *reproducibility* of the workflow (Baumer, Cetinkaya-Rundel, Bray, Loi, & Horton, 2014), since every time the document is generated from R Markdown, the underlying code for data analysis is rerun to generate the embedded output. Generating the document is essentially reproducing the analysis of data.

Supporting Reproducibility

A Reproducible analysis is an analysis with results that can be guaranteed to be reproduced from raw data anywhere by anybody (Berez-Kroeker et al., 2018). Besides rerunning analysis to generate results every time, two other features make R Markdown a good tool for facilitating a reproducible workflow:

1. R Markdown is plain text

Plain text format, contrary to binaries such as MS Word, doesn't require specialised (and often propriety) software to open, hence facilitates the openness of science. Plain text also makes the file easiler to "version control", i.e, keeping the history of modifications, or versions, of the file by version control softwares.

2. Python support

The new R package reticulate (Allaire, Ushey, & Tang, 2018) enhances the ability of Python integration in R. It is now possible to run Python in R console. The new Python engine enabled by reticulate also solved a major drawback in previous versions of R Markdown – Python variables are shared across different code chunks, i.e., Python code chunks share states in R Markdown. This

gives R Markdown the same power as Jupyter notebook.

Integrating R and Python is especially important for Linguistics, as many actively developed packages and libraries for Linguistics are written in Python. Even softwares like Praat (Boersma, 2002) has a third-party support in Python, which allows accessing low-level functions in Praat with Python (Jadoul, Thompson, & de Boer, 2018). Some tasks that R certainly does better than Python are data manipulation, visualization and report generation, hence, integrating R and Python combines the strengths of both languages. Here, R Markdown acts as a “glue”, combining different parts of analysis together into an integrated whole.

Wide Range of Output Formats and Styles

R Markdown supports a variety of output formats, owing to its foundation, Pandoc (MacFarlane, 2013). Some of the supported formats are MS Word, MS Powerpoint, LaTeX, PDF, and HTML. There are also multiple styles of document support, such as slides, books, journal papers³, and even websites. This large variety of output formats enables authors to publish their works through different formats with the same underlying R Markdown file.

It can be argued that the most prominent output format is HTML. In this Digital Age, the web becomes a popular, if not dominant, way to distribute publications. Web pages enable displaying more varieties of contents, such as GIF (animated figures) and tables with search bars, thus enhancing the ability to convey ideas. With research becoming more complex, traditional medium might not be enough to present the results. For example, it might be useless to display a complex 3D graph in a static PDF, but using GIF can facilitate the visualizing of 3D graphs, which can only be embedded in HTML files. R Markdown’s native support of HTML output makes it a valuable tool for communicating – the explanatory text is written directly with the dynamic visual elements, rather than using links to link to external files or web pages.

³For a list of supported journal templates, see <https://github.com/rstudio/rticles>.

With the ability to generate HTML outputs easily, authors also gain the ability of self-publishing the content through web, making resources available to a wider audience. This is especially useful for educational purposes in academia.

Making R Markdown Suitable for Linguistics

The power of R Markdown as an authoring tool that facilitates an integrated workflow in Linguistics comes from R's extensibility. By using R extensions, or R packages, R Markdown can be turned into a specialized tool for writing Linguistics-related documents. Below introduces two examples that reduce the burden of writing Linguistics-related documents in R Markdown.

Bibliographies and Citations

It is necessary to insert citations when writing articles for journal submission, and many use EndNote, a reference management software, together with MS Word to accomplish this. R Markdown has native support for inserting and formatting citations and bibliographies, using a citation syntax provided by Pandoc (RStudio, 2018). With R's extensibility, the experience of inserting citations can become more comfortable. For example, the R package *citr* (Aust, 2017) lets authors insert citations through a GUI interface, where authors can search information about the articles (author, year, titles etc.) they want to insert.
